

MAXIMIZING & VALIDATING ULTIMATE CAPACITY IN HIGH STRENGTH APPLICATIONS

BY EDWARD NIEDOSPIAL
TECHNICAL DIRECTOR - TRANSMISSION

INMR 2019

SUSPENSION & TENSION INSULATORS

- Primary load = tensile
- Not limited by section length
- End fittings governed by Standards
- Easily Quantifiable
- Established 3rd Party Test Protocol

End Fitting Pull-off

End Fitting Break

Rod Shatter

TENSILE RATINGS

Defined in Standards / Included on Product cut sheet

- SML = Specified Mechanical Load = Ultimate Rated Load
- RTL = Routine Test Load = Working Load
 - 50% of SML
 - Customer Defined

Not Defined in a Standard / Not on Product cut sheet

- TFL = Tensile Failure Load – actual failure load
- Lower Control Limit – Minimum performance criteria
 - *SPC – Statistical Process Control*
 - *Function x% of the SML Rating*
- Damage Limit – damage starts to occur
 - *End fitting elongation / deformation*
 - *Fiberglass strands breaking*
 - *Function x% of the TFL not SML*

20%	36,000 lbs	160 kN
Average Tensile Failure Load		
10%	33,000 lbs	147 kN
Lower Control Limit		
SML	30,000 lbs	133 kN
Ultimate Rated Tensile Load		
Damage Limit		
RTL	15,000 lbs	67 kN
Working Tensile Load		

20%	60,000 lbs	267 kN
Average Tensile Failure Load		
10%	55,000 lbs	245 kN
Lower Control Limit		
SML	50,000 lbs	222 kN
Ultimate Rated Tensile Load		
Damage Limit		
RTL	25,000 lbs	111 kN
Working Tensile Load		

The 10% Lower control limit and 20% Average tensile failure are selected at random, for reference only in this presentation

TENSILE RATINGS

20%	36,000 lbs	160 kN
Average Tensile Failure Load		
10%	33,000 lbs	147 kN
Lower Control Limit		
SML	30,000 lbs	133 kN
Ultimate Rated Tensile Load		
Damage Limit		
RTL	15,000 lbs	67 kN
Working Tensile Load		

Why do we need a Lower Control Limit?

- Target minimum tensile load the MFG would use to develop a controlled & repeatable crimp process.
- Helps define SML
- Safety Factor / Extreme Load Event
- Which 30k SML is better?
 - Ultimate failure load = 30,001 lbs.
 - Ultimate failure load = 36,000 lbs.
- Damage Limit as a Function of TFL (Not SML)
 - Assume lowest TFL = 34,000 lbs.
 - 75% of lowest TFL = 25,500 lbs.
 - 10,500 > RTL
- TWL = Tensile Withstand Load = 24,000 lbs.
 - Maximum load this insulator can withstand without compromising original strength rating.
 - Consider as a new drawing rating to be defined by MFG.

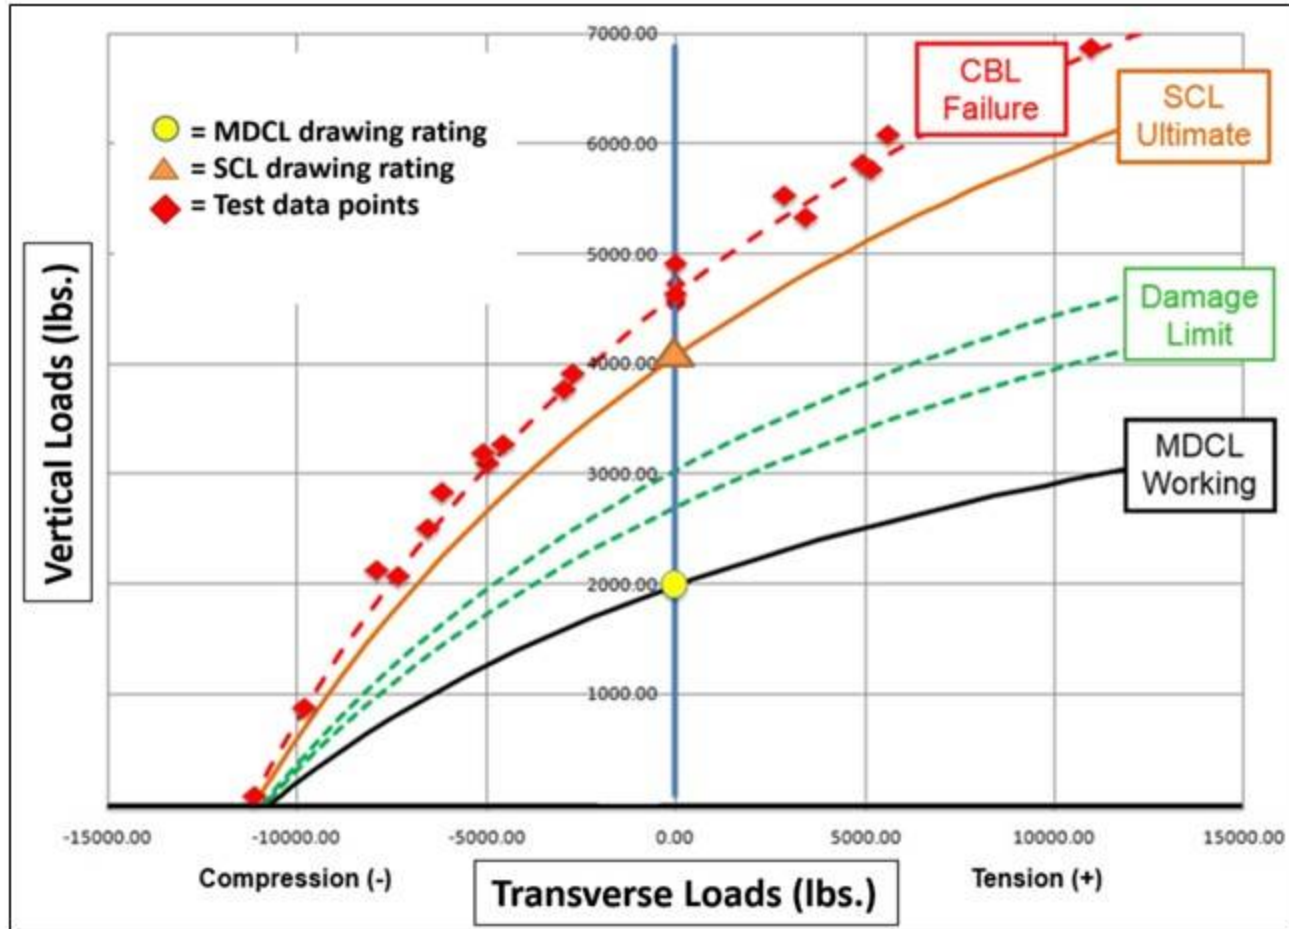

CANTILEVER LOADING OF POST INSULATORS

- Post insulators are not selected by a mechanical rating (SCL)
- Cantilever Strength is determined by the core rod Diameter & Length of the post.
- Need a balance between Mechanical & Electrical performance.
- Transfer loads from the conductor through the post into the tower.
- The base connection is very critical to the strength of the post.
- Load Curves are required for line post and braced post.
- No Industry default for a load curve
- No Industry defined test / validation procedures
- Requires many “Combined Load” cases to validate the load curve. There is no single mechanical test.

- Post Tip Deflection
- Buckling Limit of the Post
- Safety Factors

LOAD CURVES / RATINGS / VALIDATION

- SCL = Specified Cantilever Load
 - Ultimate Drawing Rating
 - SCL = 4,000 lbs.
- MDCL = Maximum Design Cantilever Load
 - 50% of SCL = 2,000 lbs. [2x Safety]
 - 40% of SCL = 1,600 lbs. [2.5x Safety]
- Transverse Loads – Compression & Tension
 - Compression = Negative side of curve
 - Tension = Positive side of curve
- Longitudinal Loads
- CBL = Cantilever Breaking Load
 - Actual load at which the post fails.
 - Failure Mode is not always easy to ID
 - Should be some % above the SCL.
 - Safety Factor applied to Ultimate Load
 - MDCL can remain 50% of SCL
- Damage Limit
 - Function of the CBL

MAXIMIZING CANTILEVER APPLICATIONS

Line Post Insulators

- Increase core rod diameter
- Improve the base strength
- Add a brace insulator to make a braced post.

Braced Post Insulators

- Vertical Capacity – Increase Brace SML
- Transverse Capacity – Increase LP rod diameter
- Load Curve – Combined Loads
- Traditional Braced Post Limitations
 - Line End Fitting
 - Tower Connection / Base – Longitudinal Loading

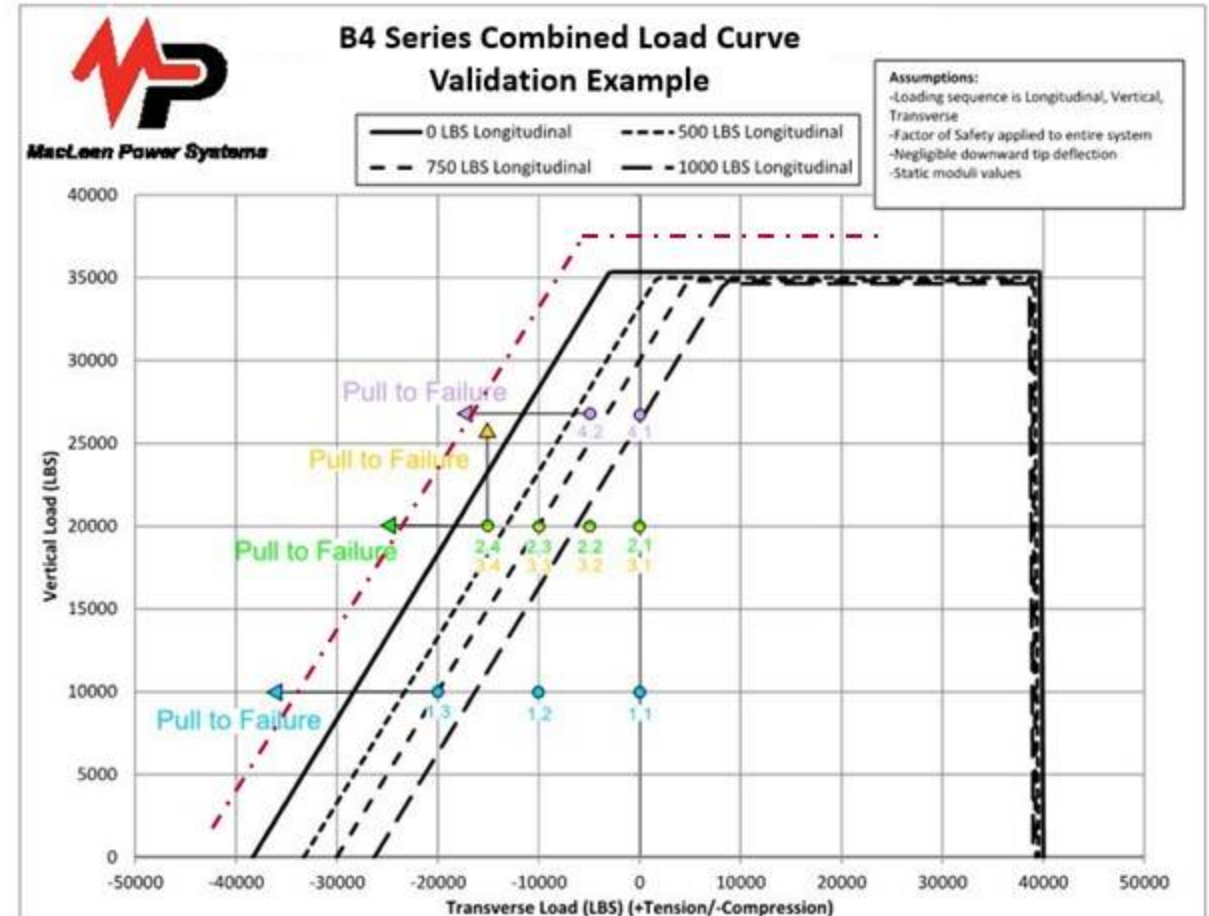

High Strength Braced Post Insulators

- Traditional limits overcome
- Higher Strength = Longer Spans

TESTING AND VALIDATION OF THE LOAD CURVE

- Multi-Axis Test Procedures
 - Vertical, Transverse, Longitudinal Loads
 - Longitudinal Resistance
 - Field Conditions / Storm Loading
 - Final Load to Failure
 - Failure Mode – Easy to ID
- CBL Data Points to confirm SCL Rating
- SCL Rating = Buckling Limit of Rod
 - Load at which post transitions from “Rigid” to “Flexible”
